03. Project Design

System Architecture

PocketSmart AI can be organized into four main layers: user interface, application/backend logic, AI service integration, and data/configuration.

The frontend is responsible for pages, forms, navigation, validation messages, and displaying budget information.

The backend or application layer handles requests, business rules, calculations, and communication with the AI service.

The AI integration receives structured user context and produces recommendation text that can be displayed by the frontend.

03. Project Design

User Interface Design

A landing or sign-in page can introduce the application and provide access to the main application.

The home dashboard should provide a clear entry point to budget planning.

Budget forms should use labels, input fields, category selections, and clear action buttons.

Recommendation results should be presented in readable sections rather than as one large block of text.

Navigation should remain consistent across the main pages.

03. Project Design

Data Flow & AI Design

Step 1: the user enters budget information.

Step 2: the application validates and organizes the input.

Step 3: budget calculations are performed where required.

Step 4: relevant structured information is passed to the AI recommendation component.

Step 5: the generated recommendation is returned to the application.

Step 6: the result is displayed to the user together with relevant budget information.

The AI should be treated as a recommendation component; calculations that require exact arithmetic should be performed by deterministic application logic.
