05. Project Development

Development Structure

The project should be developed as a connected application rather than as isolated screens.

The frontend handles presentation and user interaction. Application/backend logic handles validation, calculations, and API communication. AI integration provides recommendation generation.

Configuration values such as API keys should not be hard-coded into source files and should instead be stored using the project's environment-configuration approach.

05. Project Development

Core Development Modules

Authentication module: provides sign-in or access control if included in the implementation.

Dashboard module: provides the main entry point and budget overview.

Budget planner module: collects budget amount, categories, planned spending, and related information.

Recommendation module: sends relevant context to the Generative AI service and presents the response.

Validation module: checks user inputs and prevents incomplete or invalid requests.

UI/navigation module: connects the application pages and maintains a consistent experience.

05. Project Development

Development Practices

Use clear names for files, components, functions, and variables.

Keep reusable UI elements separate from page-specific logic.

Separate secrets and environment configuration from source code.

Test each feature after implementation instead of waiting until the end.

Handle API failures and invalid inputs with user-friendly messages.

Keep the final folder structure organized so the application can be installed and demonstrated consistently.
